Questions 1-2 are about noisy targets.

Consider the bin model for a hypothesis h that makes an error with probability μ in approximating a deterministic target function f (both h and f outputs $\{-1,+1\}$). If we use the same h to approximate a noisy version of f given by

$$P(\mathbf{x},y)=P(\mathbf{x})P(y|\mathbf{x})$$

$$P(y|\mathbf{x})=\begin{cases}\lambda & y=f(\mathbf{x}) \quad \mu \\ 1-\lambda & \text{otherwise} \quad (1-\mu)\end{cases}$$

What is the probability of error that h makes in approximating the noisy target y?

$\lambda\mu+(1-\lambda)(1-\mu)$.

- $1-\lambda$
- μ
- $\lambda(1-\mu)+(1-\lambda)\mu$
- $\boxed{\lambda\mu+(1-\lambda)(1-\mu)}$
- none of the other choices

10
points

2。

Following Question 1, with what value of λ will the performance of h be independent of μ?

獨立

0

1

0 or 1

$\boxed{0.5}$

none of the other choices

$\lambda\mu + (1-\lambda)(1-\mu)$ 要與 μ 無關

$\Rightarrow \lambda = 1-\lambda \Rightarrow \lambda = 0.5$

Questions 3-5 are about generalization error, and getting the feel of the bounds numerically. Please use the simple upper bound $N^{d_{\mathrm{vc}}}$ on the growth function $m_{\mathcal{H}}(N)$, assuming that $N \geq 2$ and $d_{vc} \geq 2$.

For an $\mathcal{H}$ with $d_{\mathrm{vc}} = 10$, if you want 95% confidence that your generalization error is at most 0.05, what is the closest numerical approximation of the sample size that the VC generalization bound predicts?

$420,000$

$440,000$

$\boxed{460,000}$

$480,000$

$500,000$

$0.05 \leq 4(2N)^{10} \exp(-\frac{1}{8} 0.05^2 N)$

There are a number of bounds on the generalization error ϵ, all holding with probability at least $1-\delta$. Fix $d_{\text{vc}}=50$ and $\delta=0.05$ and plot these bounds as a function of N. Which bound is the tightest (smallest) for very large N, say $N=10,000$?

Note that Devroye and Parrondo & Van den Broek are implicit bounds in ϵ.

- Original VC bound: $\epsilon \leq \sqrt{\frac{8}{N}\ln\frac{4m_{\mathcal{H}}(2N)}{\delta}}$ 0.63
- Rademacher Penalty Bound: $\epsilon \leq \sqrt{\frac{2\ln(2Nm_{\mathcal{H}}(N))}{N}}+\sqrt{\frac{2}{N}\ln\frac{1}{\delta}}+\frac{1}{N}$ 0.33
- Parrondo and Van den Broek: $\epsilon \leq \sqrt{\frac{1}{N}\left(2\epsilon+\ln\frac{6m_{\mathcal{H}}(2N)}{\delta}\right)}$ 0.224
- Devroye: $\epsilon \leq \sqrt{\frac{1}{2N}\left(4\epsilon(1+\epsilon)+\ln\frac{4m_{\mathcal{H}}(N^2)}{\delta}\right)}$ 0.215
- Variant VC bound: $\epsilon \leq \sqrt{\frac{16}{N}\ln\frac{2m_{\mathcal{H}}(N)}{\sqrt{\delta}}}$ 0.86

10 points

5。
Continuing from Question 4, for small N, say $N=5$, which bound is the tightest (smallest)?

- Original VC bound 13.83
- Rademacher Penalty Bound 7.04
- Parrondo and Van den Broek 4.7
- Devroye 4.9
- Variant VC bound 16.2

In Questions 6-11, you are asked to play with the growth function or VC-dimension of some hypothesis sets.

What is the growth function $m_{\mathcal{H}}(N)$ of "positive-and-negative intervals on $\mathbb{R}$ "? The hypothesis set $\mathcal{H}$ of "positive-and-negative intervals" contains the functions which are $+1$ within an interval $[\ell, r]$ and -1 elsewhere, as well as the functions which are -1 within an interval $[\ell, r]$ and $+1$ elsewhere.

For instance, the hypothesis $h_1(x) = \mathrm{sign}(x(x-4))$ is a negative interval with -1 within $[0, 4]$ and $+1$ elsewhere, and hence belongs to $\mathcal{H}$. The hypothesis $h_2(x) = \mathrm{sign}((x+1)(x)(x-1))$ contains two positive intervals in $[-1, 0]$ and $[1, \infty)$ and hence does not belong to $\mathcal{H}$.

- $\boxed{N^2 - N + 2}$
- N^2
- $N^2 + 1$
- none of the other choices.
- $N^2 + N + 2$

-1 0 1

$2\left(C_2^{N+1}\right) - 2(N-1)$

$= (N+1)N \quad -2N+2$

$= N^2 - N + 2$

10 points

7。

Continuing from the previous problem, what is the VC-dimension of the hypothesis set of "positive-and-negative intervals on $\mathbb{R}$ "?

- $\boxed{3}$
- 4
- 5
- ∞

$m_H(N) = N^2 - N + 2$

$m_H(1) = 1 - 1 + 2 = 2 = 2^1$

$m_H(2) = 2^2 - 2 + 2 = 4 = 2^2$

$m_H(3) = 3^2 - 3 + 2 = 8 = 2^3 \leftarrow$

$m_H(4) = 4^2 - 4 + 2 = 14 \neq 2^4$

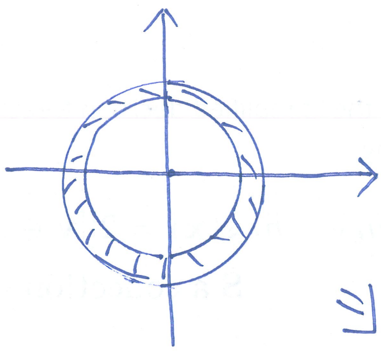
What is the growth function $m_{\mathcal{H}}(N)$ of "positive donuts in $\mathbb{R}^2$ "?

The hypothesis set $\mathcal{H}$ of "positive donuts" contains hypotheses formed by two concentric circles centered at the origin. In particular, each hypothesis is $+1$ within a "donut" region of $a^2 \le x_1^2 + x_2^2 \le b^2$ and -1 elsewhere. Without loss of generality, we assume $0 < a < b < \infty$.



- $N+1$
- $\boxed{\binom{N+1}{2}+1}$
- $\binom{N+1}{3}+1$
- none of the other choices.
- $\binom{N}{2}+1$

For Questions 16-20, you will play with the decision stump algorithm.

In class, we taught about the learning model of "positive and negative rays" (which is simply one-dimensional perceptron) for one-dimensional data. The model contains hypotheses of the form:

$$h_{s,\theta}(x) = s \cdot \mathrm{sign}(x - \theta).$$

The model is frequently named the "decision stump" model and is one of the simplest learning models. As shown in class, for one-dimensional data, the VC dimension of the decision stump model is 2.

In fact, the decision stump model is one of the few models that we could easily minimize E_{in} efficiently by enumerating all possible thresholds. In particular, for N examples, there are at most $2N$ dichotomies (see page 22 of lecture 5 slides), and thus at most $2N$ different E_{in} values. We can then easily choose the dichotomy that leads to the lowest E_{in}, where ties an be broken by randomly choosing among the lowest E_{in} ones. The chosen dichotomy stands for a combination of some "spot" (range of θ) and s, and commonly the median of the range is chosen as the θ that realizes the dichotomy.

In this problem, you are asked to implement such and algorithm and run your program on an artificial data set. First of all, start by generating a one-dimensional data by the procedure below:

(a) Generate x by a uniform distribution in $[-1, 1]$.

(b) Generate y by $f(x) = \tilde{s}(x)$ + noise where $\tilde{s}(x) = \mathrm{sign}(x)$ and the noise flips the result with 20% probability.

For any decision stump $h_{s,\theta}$ with $\theta \in [-1, 1]$, express $E_{out}(h_{s,\theta})$ as a function of θ and s.

- $0.3 + 0.5s(|\theta| - 1)$
- $0.3 + 0.5s(1 - |\theta|)$
- $0.5 + 0.3s(|\theta| - 1)$

- $0.5 + 0.3s(1 - |\theta|)$
- none of the other choices

---

Decision stumps can also work for multi-dimensional data. In particular, each decision stump now deals with a specific dimension i , as shown below.

$$h_{s,i,\theta}(\mathbf{x}) = s \cdot \text{sign}(x_i - \theta).$$

Implement the following decision stump algorithm for multi-dimensional data:

a) for each dimension $i = 1, 2, \cdots, d$, find the best decision stump $h_{s,i,\theta}$ using the one-dimensional decision stump algorithm that you have just implemented.

b) return the "best of best"' decision stump in terms of E_{in} . If there is a tie , please randomly choose among the lowest-E_{in} ones

The training data $\mathcal{D}_{train}$ is available at:

https://www.csie.ntu.edu.tw/~htlin/mooc/datasets/mlfound_math/hw2_train.dat

The testing data $\mathcal{D}_{test}$ is available at:

https://www.csie.ntu.edu.tw/~htlin/mooc/datasets/mlfound_math/hw2_test.dat

Run the algorithm on the $\mathcal{D}_{train}$. Report the E_{in} of the optimal decision stump returned by your program. Choose the closest option.
